## Linear Classification

$\mathbf{w}^{\top} \mathbf{x}_{\mathbf{i}}$ is the classifier score for the instance $\mathbf{x}_{\mathbf{i}}$
The score can be used in different ways to make a classification.

- Perceptron: output positive class if score is at least 0, otherwise output negative class
- Today: output the probability that the instance belongs to a class

## Activation Function

An activation function for a linear classifier converts the score to an output.

Denoted $\phi(z)$, where $z$ refers to the score, $\mathbf{w}^{\top} \mathbf{x}_{\mathbf{i}}$

## Activation Function

Perceptron uses a threshold function:

$$
\phi(z)=\left\{\begin{array}{r}
1, z \geq 0 \\
-1, z<0
\end{array}\right.
$$

## Activation Function

The logistic function is a type of sigmoid function (an S -shaped function)

## Activation Function

Logistic function:

Outputs a real number between 0 and 1
Outputs 0.5 when $z=0$
Output goes to 1 as $z$ goes to infinity
Output goes to 0 as $z$ goes to negative infinity

Quick note on notation: $\exp (z)=e^{z}$

## Logistic Regression

A linear classifier like perceptron that defines...

- Score: $\mathbf{w}^{\boldsymbol{\top}} \mathbf{x}_{\mathbf{i}} \quad$ (same as perceptron)
- Activation: logistic function (instead of threshold)

This classifier gives you a value between 0 and 1, usually interpreted as the probability that the instance belongs to the positive class.

- Final classification usually defined to be the positive class if the probability $\geq 0.5$.

## Logistic Regression

Confusingly:
This is a method for classification, not regression.

It is regression in that it is learning a function that outputs continuous values (the logistic function), BUT you are using those values to predict discrete classes.

## Logistic Regression

Considered a linear classifier, even though the logistic function is not linear.

This is because the score is a linear function, which is really what determines the output.

## Learning

How do we learn the parameters w for logistic regression?

Last time: need to define a loss function and find parameters that minimize it.

## Probability

Because logistic regression's output is interpreted as a probability, we are going to define the loss function using probability.

For help with probability, review OpenIntro Stats, Ch 2.

## Probability

A conditional probability is the probability of a random variable given that some variables are known.
$P(Y \mid X)$ is read as "the probability of $Y$ given $X$ " or "the probability of $Y$ conditioned on $X$ "

The variable on the left hand side is what you want to know the probability of.
The variable on the right-hand side is what you know.

## Probability

$P\left(y_{i}=1 \mid \mathbf{x}_{\mathbf{i}}\right)=\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathbf{i}}\right)$
$P\left(y_{i}=0 \mid \mathbf{x}_{\mathbf{i}}\right)=1-\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathbf{i}}\right)$

Goal for learning: learn w that makes the labels in your training data more likely

- The probability of something you know to be true is 1 , so that's what the probability should be of the labels in your training data.

Note: the convention for logistic regression is that the classes are 1 and 0 (instead of 1 and -1 )

## Learning

$$
P\left(y_{i} \mid \mathbf{x}_{\mathbf{i}}\right)=\phi\left(\mathbf{w}^{\top} \mathbf{x}_{i}\right)^{y_{i}} *\left(1-\phi\left(\mathbf{w}^{\top} \mathbf{x}_{i}\right)\right)^{1-y_{i}}
$$

## Learning

$$
\begin{gathered}
P\left(y_{i} \mid \mathbf{x}_{\mathrm{i}}\right)=\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathrm{i}}\right)^{y_{i} *}\left(1-\phi\left(w^{\top} x_{i}\right)\right)^{1-y_{i}} \\
\text { if } y_{i}=1
\end{gathered}
$$

## Learning

$$
\begin{gathered}
P\left(y_{i} \mid \mathbf{x}_{i}\right)=\phi\left(w^{\top} x_{i}\right)^{y_{i} *}\left(1-\phi\left(\mathbf{w}^{\top} \mathbf{x}_{i}\right)\right)^{1-y_{i}} \\
\text { if } y_{i}=0
\end{gathered}
$$

## Learning

$$
P\left(y_{i} \mid \mathbf{x}_{\mathbf{i}}\right)=\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathbf{i}}\right)^{y_{i}} *\left(1-\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathbf{i}}\right)\right)^{1-y_{i}}
$$

or

$$
\log P\left(y_{i} \mid \mathbf{x}_{\mathbf{i}}\right)=y_{i} \log \left(\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathbf{i}}\right)\right)+\left(1-y_{i}\right) \log \left(1-\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathbf{i}}\right)\right)
$$

Taking the logarithm (base e) of the probability makes the math work out easier.

## Learning

$\log P\left(y_{i} \mid \mathbf{x}_{\mathbf{i}}\right)=y_{i} \log \left(\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathbf{i}}\right)\right)+\left(1-y_{i}\right) \log \left(1-\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathbf{i}}\right)\right)$

This is the log of the probability of an instance's label $y_{i}$ given the instance's feature vector $\mathbf{x}_{i}$

What about the probability of all the instances?

$$
\sum_{i=1}^{N} \log P\left(y_{i} \mid \mathbf{x}_{i}\right)
$$

This is called the log-likelihood of the dataset.

## Learning

Our goal was to define a loss function for logistic regression. Let's use log-likelihood... almost.

A loss function refers specifically to something you want to minimize (that's why it's called "loss"), but we want to maximize probability!

So let's minimize the negative log-likelihood:

$$
\mathrm{L}(\mathbf{w})=\sum_{\mathrm{i}=1}^{\mathrm{N}}-\log \mathrm{P}\left(\mathrm{y}_{\mathrm{i}} \mid \mathbf{x}_{\mathrm{i}}\right)=\sum_{\mathrm{i}=1}^{\mathrm{N}}-\mathrm{y}_{\mathrm{i}} \log \left(\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathrm{i}}\right)\right) .\left(1-\mathrm{y}_{\mathrm{i}}\right) \log \left(1-\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathbf{i}}\right)\right)
$$

## Learning

We can use gradient descent to minimize the negative log-likelihood, L(w)

The partial derivative of $L$ with respect to $w_{j}$ is:

$$
\mathrm{dL} / \mathrm{dw}_{\mathrm{j}}=\sum_{\mathrm{i}=1}^{\mathrm{N}} \mathrm{x}_{\mathrm{ij}}\left(\mathrm{y}_{\mathrm{i}}-\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathrm{i}}\right)\right)
$$

## Learning

We can use gradient descent to minimize the negative log-likelihood, L(w)

The partial derivative of $L$ with respect to $w_{j}$ is:

$$
\begin{gathered}
\mathrm{dL} / \mathrm{dw}_{\mathrm{j}}=\sum_{\mathrm{i}=1}^{\mathrm{N}} \mathrm{x}_{\mathrm{ij}}\left(\mathrm{y}_{\mathrm{i}}-\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathrm{i}}\right)\right) \\
\text { if } \mathrm{y}_{\mathrm{i}}=1 \ldots
\end{gathered}
$$

The derivative will be 0 if $\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathbf{i}}\right)=1$
(that is, the probability that $y_{i}=1$ is 1 , according to the classifier)

## Learning

We can use gradient descent to minimize the negative log-likelihood, L(w)

The partial derivative of $L$ with respect to $w_{j}$ is:

$$
\begin{gathered}
\mathrm{dL} / \mathrm{dw}_{\mathrm{j}}=\sum_{\mathrm{i}=1}^{\mathrm{N}} \mathrm{x}_{\mathrm{ij}}\left(\mathrm{y}_{\mathrm{i}}-\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathrm{i}}\right)\right) \\
\text { if } \mathrm{y}_{\mathrm{i}}=1 \ldots
\end{gathered}
$$

The derivative will be positive if $\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathrm{i}}\right)<1$
(the probability was an underestimate)

## Learning

We can use gradient descent to minimize the negative log-likelihood, L(w)

The partial derivative of $L$ with respect to $w_{j}$ is:

$$
\begin{gathered}
\mathrm{dL} / \mathrm{dw}_{\mathrm{j}}=\sum_{\mathrm{i}=1}^{\mathrm{N}} \mathrm{x}_{\mathrm{ij}}\left(\mathrm{y}_{\mathrm{i}}-\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathrm{i}}\right)\right) \\
\text { if } \mathrm{y}_{\mathrm{i}}=0 \ldots
\end{gathered}
$$

The derivative will be 0 if $\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathbf{i}}\right)=0$
(that is, the probability that $y_{i}=0$ is 1 , according to the classifier)

## Learning

We can use gradient descent to minimize the negative log-likelihood, L(w)

The partial derivative of $L$ with respect to $w_{j}$ is:

$$
\begin{gathered}
\mathrm{dL} / \mathrm{dw}_{\mathrm{j}}=\sum_{\mathrm{i}=1}^{\mathrm{N}} \mathrm{x}_{\mathrm{ij}}\left(\mathrm{y}_{\mathrm{i}}-\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathrm{i}}\right)\right) \\
\text { if } \mathrm{y}_{\mathrm{i}}=0 \ldots
\end{gathered}
$$

The derivative will be negative if $\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathrm{i}}\right)>0$
(the probability was an overestimate)

## Learning

We can use gradient descent to minimize the negative log-likelihood, L(w)

The partial derivative of $L$ with respect to $w_{j}$ is:

$$
\mathrm{dL} / \mathrm{dw}_{\mathrm{j}}=\sum_{\mathrm{i}=1}^{\mathrm{N}} \mathrm{x}_{\mathrm{ij}}\left(\mathrm{y}_{\mathrm{i}}-\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathrm{i}}\right)\right)
$$

So the gradient descent update for each $w_{j}$ is:

$$
w_{j}+=\eta \sum_{i=1}^{N} x_{i j}\left(y_{i}-\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathrm{i}}\right)\right)
$$

## Learning

So gradient descent is trying to...

- make $\phi\left(\mathbf{w}^{\top} \mathbf{x}_{i}\right)=1$ if $y_{i}=1$
- make $\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathbf{i}}\right)=0$ if $\mathrm{y}_{\mathrm{i}}=0$

But there's a problem...

$$
\phi(z)=\frac{1}{1+e^{-z}}
$$

z would have to be $\infty$ (or $-\infty$ ) in order to make $\phi(z)$ equal to 1 (or 0)

## Learning

So gradient descent is trying to...

- make $\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathbf{i}}\right)=1$ if $\mathrm{y}_{\mathrm{i}}=1$
- make $\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathbf{i}}\right)=0$ if $y_{i}=0$

Instead, make
"close" to 1 or 0

Don't want to optimize "too" much while running gradient descent

## Learning

So gradient descent is trying to...

- make $\phi\left(\mathbf{w}^{\top} \mathbf{x}_{i}\right)=1$ if $y_{i}=1$
- make $\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathbf{i}}\right)$ ת 0 if $\mathrm{y}_{\mathrm{i}}=0$

Instead, make
"close" to 1 or 0

We can modify the loss function that basically means, get as close to 1 or 0 as possible but without making the w parameters too extreme.

- How? That's for next time.

## Learning

Remember from last time:

- Gradient descent
- Uses the full gradient
- Stochastic gradient descent (SGD)
- Uses an approximate of the gradient based on a single instance
- Iteratively update the weights one instance at a time

Logistic regression can use either, but SGD more common, and is usually faster.

## Prediction

The probabilities give you an estimate of the confidence of the classification.

Typically you classify something positive if $\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathbf{i}}\right) \geq 0.5$, but you could create other rules.

- If you don't want to classify something as positive unless you're really confident, use $\phi\left(\mathbf{w}^{\top} \mathbf{x}_{\mathbf{i}}\right) \geq 0.99$ as your rule.

Example: spam classification

- Maybe worse to put a legitimate email in the spam box than to put a spam email in the inbox
- Want high confidence before calling something spam

## Other Disciplines

Logistic regression is used in other ways.

- Machine learning is focused on prediction (outputting something you don't know).
- Many disciplines is it as a tool to understand relationships between variables.

What demographics are correlated with smoking?
Build a model that "predicts" if someone is a smoker based on some variables (e.g., age, education, income).

The parameters can tell you which variables increase or decrease the likelihood of smoking.
